## Abstract

Information processing and decision support system using image mining techniques is in advance drive with huge availability of remote sensing image (RSI). RSI describes inherent properties of objects by recording their natural reflectance in the electro-magnetic spectral (*ems*) region. Information on such objects could be gathered by their color properties or their spectral values in various *ems* range in the form of pixels. Present paper explains a method of such information extraction using cubical distance method and subsequent results. This method is one among the simpler in its approach and considers grouping of pixels on the basis of equal distance from a specified point in the image or selected pixel having definite attribute values (DN) in different spectral layers of the RSI. The color distance and the occurrence pixel distance play a vital role in determining similar objects as clusters aid in extracting *features* in the RSI domain.

Key words: Image mining, Feature extraction, Cubical distance, Frequent Item set, Remote sensing Image

## 1,0 Introduction

In the present paper, digital numbers (DN) values of the selected remote sensing image (RSI) is studied to understand the image mining technique to extract information. This was carried out y grouping of pixels to determine features and predicates the possible integration of applications using clustering techniques. In this context, an algorithm using cubical distance calculation method to cluster pixels is used to extract features. The classification process is implemented with the DN values obtained through pre-processing the RSI. [1]

In cubical distance method, the pixels are grouped or clustered based on the distance of their respective DN values in each layer (B, G, R). The estimated distance helps to group pixels having similar distance value as group or clusters [2]. The data input in the form of macro array, position of each pixel is represented as x, y followed by the respective DN values in the three layers (B,G,R). In this method, distance of pixels to respective cluster interval is segregated as groups, which may be labeled as specific feature may show similar distance criterion [3]. To appreciate the inherent influence of such distance measures, three methods are identified under cubical distance method such as *"from the origin"*, *"from the first position of the selected ROI"* and *"frequently occurred pixel"*. Algorithms for these three methods are designed and implemented to cluster pixels and in turn, extract features.

### 2.0 Methodology

Methodology adopted in the study is as follows:

- i.Select appropriate Remote sensing Image (RSI) to identify landuse features
- ii.Preprocess the RSI for geometrical error so that the image represents the ground condition.
- iii.Convert the multi layer image into two dimensional Digital number (DN) values as macro-array data.
- iv.Determine the distance of the pixel using cubical distance determination methods
  - a. From the origin (0,0,0)
  - b. From the first point of the Region of Interest
  - c. From the frequent occurrence point in the ROI
- v.Implementation and clustering of pixels according to their distance for the significance of results using such methods.

### 3.0 Preprocessing of RSI

Selected RSI is preprocessed for geometrical correction so that the image represents the ground condition in real time [4]. Ground control points (GCPs) are used to carry out geometrical correction with the help of GIS (Geographic Information System) as available in the image processing software, ERDAS Imagine. The geometrically corrected image was later converted into a processable macro array data format.

#### 3.1 Macro Array Data format

The pixels in the RSI image have specific digital numbers (DN) as their attributes, which vary with the spectral range (Blue, Green, Red and Infrared). Such spectral variations are exploited in image mining so that specific features are clustered individually. In the present study, any three layers mostly RGB are selected from the RSI and converted into macro-array format (X,Y, layer1 value, layer2 value, layer3 value), where X and Y stands for the position of the pixel and layer1, layer2 and layer 3 are the attribute DN values of the pixel in different spectral layers. A sample of extracted DN values in specific data format is shown below.

1,4, 146, 128, 139; ....]

### 4.0 Procedure for Cubical Distance Method

Procedure for classification using cubical method

- i. Select the RSI for preprocessing
- ii. Preprocess the captured RSI for analysis
- iii. Select the ROI
- iv. Convert the ROI into cubical digital array using macro array process
- v. Calculate the distance for the chosen three methods:

a. Assign the P as (0,0,0) origin value and calculate the distance of each existing pixel from the origin using the formula  $OP = \sqrt{((0-a)^2 + (0-b)^2 + (0-c)^2)}$ .  $OP = \sqrt{a^2 + b^2 + c^2}$ 

b. Assign P1 as first pixel of the ROI  $(x_1, y_1, z_1)$  and distance for another point (P2) as  $(x_2, y_2, z_2)$  value and calculate the distance of each existing pixel from the first pixel of the ROI using the formula P1Pi =  $\sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$ 

c. Assign the highest Frequency as a first point PF  $(x_1, y_1, z_1)$  and distance for another point as $(x_2, y_2, z_2)$ . Calculate the distance of the each existing pixel from the highest Frequency pixel (PF) using the formula

 $PFPi = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}.$ 

Calculate the minimum and maximum distance. Assign the required number of clusters as input from the user

- vi. Calculate the range of distance as maximum minimum/ number of clusters
- vii. Verify the distance and compare with the range belongings
- viii. Assign the clustering index value, representing features, for each pixel as per the distance and range belongings
- ix. Group all the similar classification index values as clusters and resultant image is generated.

#### **5.0 Implementation and Result**

The selected ROI of 400 x 400 array is manipulated based on the DNs of each layer together. The coding for the ROI to determine the range values of pixels based on equal interval was carried out and executed using Matlab 7.1.

Figure 1. ROI image taken for analysis

The above-discussed algorithms are applied on the selected ROI and resultant clustering and *feature* extraction are discussed in the following and illustrated in Table 1.

A. From the Origin (0,0,0)								
Cluster	No. of Pixel	% of Pixel	Blue		Green		Red

Table 1. Clustering and DN Range values by Cubical Distance Method

C. From the first point of Frequent occurrence pixel								
Cluster	No. of Pixel	% of Pixel	Blue		Green		Red	
			Start	End	Start	End	Start	End
1	4290	26.18	84	169	45	126	34	133
2	-	-	-	-	-	-	-	-
3	896	5.47	92	107	53	67	102	85
4	4560	27.83	84	122	45	70	34	79
5	3725	22.74	89	136	46	81	33	90
6	2239	13.67	103	145	63	91	154	113
7	584	3.56	105	159	63	90	178	119
8	82	0.50	143	161	125	118	120	129

All the above outputs in the form of statistical output for all the three methods are also generated as graphical map output, which is illustrated below in Figure 2. The table1 depicts the statistical discussion above in a more lucid manner. Waterbody, obviously, present in the center part of image is clearly brought out in the first cluster image of all the three methods – from the origin, from the first pixel and from the frequent occurrence pixel of the selected ROI, irrespective of various methods of distance estimation for clustering. In the first cluster of the image obtained from the first point, agricultural pattern is seem to be more clearly brought out compared to the other two methods. A dense patch of pixels seen in northeastern and southwestern parts of the image may indicate presence of crop land, which are seen sporadically in the other two methods. Since there is no DN range value of pixel in second and third clusters of origin method and second cluster in frequent occurrence method, output image are not found. This implies the absence of pixel range values in that particular cluster while distance is calculated. Most of the vegetation such as crop land, scrub and plantation is visible in the second and third clusters of the *first point* method and fourth and fifth clusters of the *FIS* method whereas vegetation mostly crop land is seen in the sixth and seventh clusters of the origin method. Except the first cluster, waterbody is conspicuously absent in all the other cluster in all the three methods, though its shape is retained due to the presence of soil moisture and scrub around the waterbody. Presence of scrub and barren soil is well brought out in the seventh and eighth clusters of the first point method. Similarly, existence of barren land around the waterbody is seen in the fifth cluster of the first method and fourth cluster in the third method.

Thus, cubical distance estimation among pixels for feature extraction using various methods - from the origin, from the first pixel and frequent item pixel – enumerate the efficiency of segregating pixels as groups, which may inferred with presence of certain predominance of certain feature such as crop, scrub, waterbody, fallow, plantation and so on.

From the above analysis, it is observed that crop feature has a range value of 123, 112, 78 in BGR respectively. Similarly, barren land shows 125,95,100, fallow land as 120,80,83, scrub shows 56, 68, 120, water body shows 85,45,35, soil moisture as 118,85,90 and plantation shows 106,70,85 in that order as shown in the above table that are identified and selected with the help of domain landuse expertise.

## 6.0 Conclusion

Feature extraction using "*distance*" as the criterion is significantly efficient in clustering the pixels of similar character and thus enables a better clustering and grouping of features. Cubical distance estimation among pixels for feature extraction using various methods - from the origin, from the first pixel and frequent item pixel – enumerate the efficiency of segregating pixels as groups, which may inferred with presence of certain predominance of features such as crop, scrub, fallow, plantation and so on. Such feature extraction since based on distance alone as parameter without any other conditionaliities may show certain "bias" or "mixing up of pixels" either overlapping or completely strange pixels. Even though such limitations exist they do not warrant any less in significance of feature extraction, since the method attempts to extract features by determining the DN range values.
